CNN: The CNN model encountered kernel crashes during training but exhibited a high success rate upon successful execution.

Transfer Learning: The Transfer Learning model achieved a perfect success rate of 20 out of 20 images.

Discussion

ANN Performance:

The ANN model's relatively lower success rate suggests that it may not be effective in capturing complex patterns and features in the image data.

ANN models often struggle with image classification tasks due to their inability to handle spatial information effectively.

CNN Performance:

Despite experiencing kernel crashes during training, the CNN model demonstrated promising performance in terms of success rate.

CNNs are well-suited for image classification tasks, as they can automatically learn hierarchical features from raw pixel data.

Transfer Learning Performance:

The Transfer Learning model, which leveraged pre-trained CNN architectures, achieved the highest success rate. Transfer Learning allows for the transfer of knowledge learned from one task/domain to another, thereby reducing the need for extensive training data.

Conclusion

In conclusion, the Transfer Learning model outperformed both the ANN and CNN models in classifying images of apples and bananas. While the ANN model showed limited success, the CNN model exhibited potential despite encountering technical difficulties during training. Future research could focus on optimizing the CNN architecture and addressing stability issues to harness its full potential. Additionally, exploring more advanced transfer learning techniques could further improve classification performance in similar tasks.
